Modeling the Performance of Humanitarian Supply Chain Management with the Help of Partial Least Squares (PLS)

Ahmad Tavakoli[1] , **Maryam Aliei**[2]

Original Article

Abstract

INTRODUCTION: Increasing the incidence of natural disasters around the world has led to increased concerns about the social and economic development of developed countries. Natural disasters are inevitable, but they can be taken to reduce their negative impacts on countries. Organizations involved in managing these crises must regulate their supply chain and make the necessary changes to improve the performance of the humanitarian supply chain.

METHODS: Data analysis by partial least squares method (PLS) was performed using smart-pls2 software and a researcher-made questionnaire with 25 questions that examined six structures. In this research, 320 questionnaires have been distributed. In the statistical population of the survey, there are military centers, fire brigades, Omer Crescent population, emergency 115, crisis management and renovation committee in the parliament, governorate, municipalities, supply chain managers, Active practitioners in this field, subject specialists (reference persons and perpetrators in this field), and other members of the organizations involved in rescue and rescue operations in Tehran (randomly selected from the 22 areas). Eventually, 193 people were involved in relief and rescue operations. The reliability of the model has been investigated and verified through three ways of evaluating factor load coefficients, Cronbach's alpha coefficients, composite reliability (CR). The average variance extracted (AVE) values are greater than 0.5, and CR values are larger than AVEs. That means convergent validity. Also, the mean of the AVE for each structure is greater than 0.50 and this is a sign of convergent validity.

FINDINGS: For the model, GOF is 0.56; that means the model has a great fit. The statistics above show that the proposed model is suitable for data collection. In general, the proposed model confirms the relationship between the use of information technology, mutual trust, flexibility, agility, adaptability and performance of the humanitarian supply chain. Fit statistics have four indicators: Goodness of Fitness (GFI) of 0.92, Fitted Goodness Index (AGFI) of 0.9, Root RMSEA error of 0.04, and 360.88 x 360 times. Finally, the ratio of k^2 to the degree of freedom for 1.38 is obtained, indicating the good of fitness of the model fit with the data. With the aid of p-values and T-Values 8 hypotheses were confirmed in this modeling.

CONCLUSION: The results show that the agility and flexibility of organizations in the humanitarian supply chain are related to the use of information technology and organizational trust, which in turn affects performance.

Keywords: Human Resource Supply Chain; Performance; Agility; Flexibility; Information Technology

Introduction

In recent years, physicians and academics have paid a great attention to the humanitarian aid supply chains aiming to improve performance in rescue operations. With the increasing rate of natural disasters such as earthquakes, floods, storms and hurricanes, fires, plane crashes, and shipwrecks, there is a growing concern among the countries. The casualties and ruins caused by these disasters with a natural or human origin may take place at any point in the world, and may be along with disastrous outcomes (1-3). The impact of the natural disasters on the human life is evident and these disasters always impose huge damages on the economy of the countries.

Assuming that the demands are constantly changing and there are differences in the magnitude and severity of the disaster as well as the disaster area, prior resources and planning may not be effective for all events that may take place. In today's world, events occurring in one country may influence other countries as well. For example, global financial crises affect every country in the world in practice. To overcome these circumstances, all beneficiaries must act in harmony. However, coordination cannot be achieved in the short term, as factors such as trust among the beneficiaries influence this coordination. Rogers et al., for instance, stated that if organizations trust each other, they would be more likely to work together (4). The coordination among the active individuals supports the proper crisis management. For example, the supplemental plans can maximize the use of the resources that are limited in terms of time, capital, and human resources.

The ability of the active individuals to respond to the varying demands in the humanitarian supply chain (HSC) is of a paramount importance. Regarding the commercial supply chain (CSC), flexibility refers to the methods in which the smooth flow of products can be guaranteed (5). In addition, the flexibility of the HSC indicates the ability of the active individuals to respond to the unexpected requirements and demands of the individuals affected by the event, which includes the speed of delivery of food, water, drugs, clothing, blankets, etc. to the affected individuals. Agility represents the power of interaction between an organization and the market for an organization (6). In this study, agility has been defined as the capability of an organization to quickly adapt to the event-induced changes in different situations. Agility is a feature of the organizations that can perceive the short-term changes in the chaotic situation caused by the events such as supply and demand fluctuations and the rapid and flexible response required to cope with these circumstances.

Utilization of the information technology (IT) is an emerging priority for organizations in managing their CSC. For instance, the IT capabilities are required in managing the knowledge, changes, assets, and the CSC. In this way, the application of IT in the HSC reduces the negative impacts of the natural disasters in the society, which is a step towards improving the economic and development conditions of the country in the long run (7-10). To understand the advantages of IT, it must be combined with other factors producing valuable sustainable resources (9,10). These factors are flexibility, agility, mutual trust, adaptability, and performance (11-13).

Mutual trust is an important property for a business which is somehow involved in the information acquisition and sharing methods. In this study, the trust among organizations involved in the disaster rescue operations process has been investigated. Regarding the relation among the organizations, the mutual trust is defined as the expectations of a company with respect to the responsibilities of the other company and the behavioral or ethical values assuming the possibility of an opportunistic behavior (14,15). Besides, adaptability has been described as the capability of changing in a given state. In this study, the adaptability has been defined with a wider context as the ability to change or adapt quickly in a timely manner in the current environment. This could include building new warehouses, changing the selection of suppliers or other service providers, or implementing the custom commercial resources which are planned in a flexible manner by adjusting the supply chain network. The application of IT enhances the mutual trust and quality of the current information among the organizations in the CSC, leading to the increased competitive performance of each organization. Moreover, agility, flexibility, IT, and particularly the CSC are all related to each other.

Furthermore, our knowledge of the relationships among the application of IT, flexibility, agility, adaptability, and performance is often limited to the concept of the CSC (16).

Examining these similar relationships in the HSC field leads to the interesting results. As the number of studies conducted on the crisis and emergencies management has increased (17-21), relatively few studies have addressed the HSC issue experimentally and quantitatively (22,23). Therefore, in this study, it has been attempted to address this important research requirement. The objective in this study was to better understand the relationships among IT, mutual trust, agility, flexibility, adaptability, and performance in the HSC field.

It has been declared the communication and coordination to be necessary to increase the transparency of the existing systems. This helps to exploit the IT systems in the incident management. Therefore, the rescue team members need to cooperate closely on natural disasters and adjust and modify or rebuild their resource chains with increasing agility, flexibility, and adaptability to the circumstances. In the rescue operations, the active individuals are from among various beneficiaries and organizations that are directly or indirectly involved in the rescue operations (1,24). To decrease the incident uncertainty risks, the organizations must continuously identify and evaluate their operating environments in order to progress. Factors that enhance the performance of the organizations during the rescue operations must be constantly examined (25). This study has presented guidance to smaller organizations to understand the important factors in upgrading the performance of the human resource chain. In this study, the relationship among the use of IT, mutual trust, flexibility, agility, and adaptability on the performance of the HSC has been presented for the first time.

These organizations must have a concordant function after the event to reduce the negative impacts of the event on the society. Collaboration between groups leads to the formation of a supply chain (SC). In a study carried out by Hall et al. (26), the SC definition proposed by Christopher and Towill (27) is quoted as saying that SC is a network of organizations that are involved in different processes and activities that produce value through higher and lower communications, in the form of products and services delivered to the end consumer.

SC and HSC is a network of members that support the flow of goods, information, and capital from the source to the end customer (28). The only difference is that the customers in the HSC include the individuals affected by the incident and the benevolent individuals who play a supporting role in improving the performance of the HSC (29-31).

The following study deals with the theoretical framework and assumptions presented in the development of the hypothesis and the theoretical framework. The study method has been outlined in the *analysis and design* section. In the *results and data analysis* section, the results of the data analysis can be observed. In the *discussion* section, the study findings are described. In addition, the *conclusion* section addresses the limitations and capacities for future studies.

Methods

This applied study was performed using the descriptive-survey method. The partial least squares (PLS) method is a path modeling method based on the univariate and multivariate regression that estimates the path coefficients and variances for the model (32). Therefore, it may have several dependent variables. To establish a relationship between the dependent and independent variables, the PLS method creates new explanatory (independent) variables. In contrast to the covariance-based structural equation modeling (SEM), the PLS method focuses on the highest variance of the dependent variables explained by the independent variables instead of reproducing the experimental covariance matrix. As with any SEM, the PLS method is comprised of a structural section indicating the relationship between the latent variables and a measurement component that reflects the relationship between the latent variables and their markers. The PLS method is highly useful for analyzing the structural models with several variables (33-37).

Flexibility is the key characteristic of an agile organization (38-40) and the application of IT is beneficial for the organizations to enhance their agility, flexibility, and performance (41-43). A conceptual model has been depicted in figure 1 to examine the relationship between the IT application and mutual trust, flexibility, agility, adaptability, and performance. In this study, the application of IT and mutual trust was not considered from the point of view of an organization, but rather from a HSC perspective.
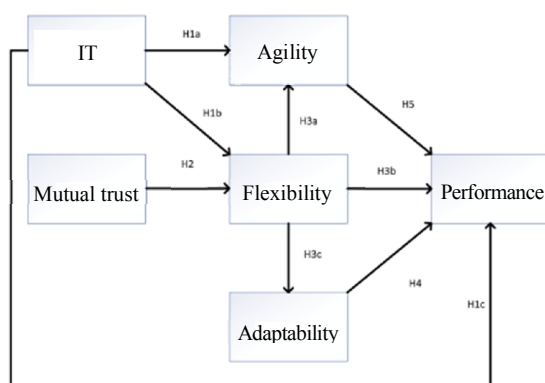

Figure 1. Conceptual model of the study

The hypotheses investigated in the current study were as follows:

Hypothesis 1a: The application of IT has a positive effect on the agility of the organizations involved in HSC.

Hypothesis 1b: The application of IT has a positive effect on the flexibility of the organizations involved in HSC.

Hypothesis 1c: The application of IT has a positive effect on the performance of the organizations involved in HSC.

Hypothesis 2: Mutual trust has a positive effect on the flexibility of the organizations involved in HSC.

Hypothesis 3a: Flexibility has a positive effect on the agility of the organizations involved in HSC.

Hypothesis 3b: Flexibility has a positive effect on the adaptability of the organizations involved in HSC.

Hypothesis 3c: Flexibility has a positive effect on the performance of HSC.

Hypothesis 4: Agility has a positive effect on the performance of HSC.

Hypothesis 5: Adaptability has a positive effect on the performance of HSC.

For this study, a survey method was employed to experimentally examine the above-mentioned relationships. According to several researchers, such as Gall et al. (44), Schneider et al. (45) and Smith and Dainty (46), the survey method is a useful tool to estimate the unobservable phenomena such as the employees' perceptions of the organization or the relationship between different processes and their proportion. In addition in this study, the guidelines provided in the studies by Flynn et al. (47) and Hair et al. (48) were followed. The data were collected and utilized to test the above-mentioned hypotheses.

The measurement tool in this study was a researcher-made questionnaire, with the items examined in the study and the questions outlined by the researcher listed in Table 1.

Table 1. Items and dimensions of the researcher-made questionnaire in accordance with the previous studies (1,12,13,25,49-51)

Variable		Questionnaire item
IT	IT1	The organization uses the transfer of IT to the international organizations.
	IT2	The organization uses the transfer of IT to the domestic organizations.
	IT3	The organization uses IT to create and store information for the future.
	IT4	The organization uses IT to manage the rescue materials.
Mutual trust	MT1	The organization believes that other beneficiaries provide the best advice for our businesses.
	MT2	The organization is able to provide honest assistance to the company suppliers.
	MT3	Our colleagues in the organization maintain the documents of conversations in the company.
Flexibility	HSF1	The ability to provide services and products at the right time and place
	HSF2	The ability to provide services and products in the minimum production time
	HSF3	Ability to change the distribution mode for the product or service
	HSF4	Organizational structure relying on the interest in collaboration
Adaptability	HSCA1	Adaptability to the cultural changes of other organizations
	HSCA2	Adaptability to the partner SC constraints
	HSCA3	Adaptability to environmental requirements
Agility	HSCAG1	Partners provide any information that may be useful.
	HSCAG2	Ability to work with key partners to improve SC
	HSCAG3	Ability to develop common plans on service support with key partners
	HSCAG4	The exchange of information is carried out regularly throughout the SC.
	HSCAG5	Increased reliability of delivery of services
	HSCAG6	Service provider satisfaction
Performance	HSCP1	Rapid response time after the disaster
	HSCP2	Availability of the appropriate medical facilities
	HSCP3	Proper management of rescue equipment
	HSCP4	Availability of a considerable amount of rescue materials
	HSCP5	Improved level of customer service

IT: Information technology; SC: Supply chain

The dimensions investigated were outlined by several researchers (1,12,13,25,49-51).

In the present study, a five-point Likert scale (1-5) was employed with the items obtained from the previously used multiple-item scales. The criteria for applying IT reflected its use in various SC activities such as inventory management, procurement, regulation, distribution, and coordination of the organizations involved in the rescue operations, which included the perceived value of the managers active in the organizations. The mutual trust criteria indicated the trust in the shared information for their mutual advantages to enhance the efficiency of the rescue operations.

The flexibility criteria enable an organization to deliver or change products or services in the shortest time with the ability to quickly change the transfer mode. The HSC adaptability criteria are indicative of the ability of the active individuals to quickly adapt to the limitations in the event coping phase, including the management of the cultural differences among the organizations regarding the constraints of a number of partners. The agility criteria reflect the levels of information sharing, cooperative work, and development planning to improve the customer service to upgrade the rescue operations efficiency. Finally, the performance criteria show the way of coping with an incident, which include the criteria for the speed of preparation of medical and auxiliary facilities.

The PLS method was employed to analyze the hypotheses proposed in this study. This technic requires less sample size compared to other modeling technics to respond to the hypotheses in the model. According to Chin and Newsted, an acceptable sample size for a multiple regression study at a test power level of 0.8, significance level of 0.05, and effect size of 0.15 is 108 (52). As a general rule, the sample size in the PLS method should be 10 times the number of the model variables (53); since there were 6 variables in this study, based on this method, the sample size had to be greater than 60.

Additionally, Barclay et al. suggested that the sample size for the PLS method should be at least ten times the maximum number of construct paths directed to a particular construct in the internal path model (54). In this model, the variables of flexibility, agility, and performance with 9 relationships had the highest level of relationship, i.e. the acceptable sample size for the current

model was 90.

To ensure the validity of the questionnaire, the specialists (professors) in the SC management field reviewed it. These professors had an experience of over 5 years and have published several research studies and case studies in the internationally accredited journals. After reviewing and submitting comments by the professors, some items were removed and redesigned for more clarity. Moreover, the questionnaire was pilot tested with 22 respondents.

For this purpose, to obtain 90 samples, 320 questionnaires were distributed in the target statistical population including military centers, fire departments, Red Crescent Society, Emergency 115, parliament committee on the crisis management and renovation, provincial government, governorate, municipalities, SC managers, physicians active in this field, subject specialists, (reference individuals and influential people in this field), and other members of the organizations involved in rescue operations in Tehran City, Iran, who were selected using the random clustering method from 22 districts. These organizations were selected based on their presence in the rescue operations as published in the media and newspapers. However, to ensure their participation in the rescue operations, the introduction section was included in the questionnaire. In case of the lack of presence of the individuals at the operation, their responses were eliminated from the study to retain the generality of the results. Then, 209 questionnaires were completed and received from those who had participated at least in one rescue mission. Of these questionnaires, 16 were excluded due to the provision of the incomplete information. Finally, 193 (60%) questionnaires, which is an acceptable rate for such surveys (55), were considered in this study. At last, the participants in the study included 193 individuals involved in the rescue operations.

Findings

Table 2 presents the demographic characteristics of the subjects, including age, experience level, and gender.

40, 22, 20, 10, and 8 percent of the responses was associated with the organizations with a personnel number of less than 50, 101-200, 50-100, 200-300, and more than 300, respectively.

As illustrated in the primary conceptual model of the study (Figure 1), the resulting variable is a

reflective variable. Moreover, for complex models in which there is little theoretical information and the analysis can be performed even with 30 questionnaires, the PLS is a very useful method.

Table 2. Demographic characteristics of the subjects

Descriptive characteristics of samples		n	%
Age (year)	Less than 30	84	44
	31-40	68	35
	41 and higher	41	21
Experience (year)	Less than 10	102	53
	10-20	48	25
	More than 20	43	22
Gender	Female	155	80
	Male	38	20

A measurement model is part of a general model that includes a variable with items about that variable. The three criteria of reliability, convergent validity (CV), and discriminant validity are exploited to examine the fitting of the models. The reliability itself is evaluated by three ways: factor load coefficients, Cronbach's alpha coefficients, and composite reliability (CR). Generally, if the Cronbach's alpha and CR values are higher than 0.8 and the average variance extracted (AVE) value is greater than 0.5, it can be declared that the measurement tool (questionnaire) has been able to well measure the desired latent variables.

In this study, the Cronbach's alpha coefficient for all constructs was higher than 0.70, as represented in Table 3 indicating a high reliability. The standardized factor loading for each item employed in this study ranged from 0.652 to 0.928. The items used in the study had content validity as the choice of the measurement items was based on a comprehensive review of the literature as well as the evaluations by the experts. Furthermore, for CV, as shown in the table, all the CR values were greater than 0.7, and the AVE values were greater than 0.5, hence the CR values are greater than the AVE values. That is, CV was confirmed.

In addition, AVE was used to examine CV for each construct, which was greater than 0.50, indicating that CV was confirmed. In addition, the Fornell and Larker criterion was employed to investigate the discriminant validity. This method implied that a construct in the model had a higher interaction with its indices in comparison to the other constructs. The discriminant validity was acceptable when the AVE value for each construct was greater than the shared variance between that construct and other constructs in the model. This issue was examined by a matrix the places of which contained the values of the correlation coefficients between the constructs and the square root of the AVE values for each construct.

Table 3. Analysis of reliability, convergent validity (CV), and discriminant validity of the model variables

Variable		Standardized factor load	P	CR	AVE	Cronbach's alpha	MSV	ASV
IT	IT1	0.885	39.106	0.923	0.750	0.889	0.04	0.02
	IT2	0.859	31.222					
	IT3	0.883	42.870					
	IT4	0.837	18.466					
Mutual trust	MT1	0.800	16.017	0.906	0.763	0.844	0.05	0.02
	MT2	0.903	39.665					
	MT3	0.914	53.243					
Flexibility	HSF1	0.868	41.884	0.952	0.832	0.932	0.04	0.03
	HSF2	0.928	65.324					
	HSF3	0.922	53.983					
	HSF4	0.928	63.013					
Adaptability	HSCA1	0.806	16.897	0.866	0.684	0.768	0.05	0.02
	HSCA2	0.885	30.805					
	HSCA3	0.786	14.984					
Agility	HSCAG1	0.817	27.763	0.945	0.743	0.930	0.06	0.03
	HSCAG2	0.906	49.095					
	HSCAG3	0.871	41.464					
	HSCAG4	0.893	59.644					
	HSCAG5	0.855	32.300					
	HSCAG6	0.825	28.48					

IT: Information technology; CR: Composite reliability; AVE: Average variance extracted; MSV: Maximum shared variance; ASV: Average shared variance

Table 4. Discriminant validity assessment matrix by Fornell and Larker method

Variable	Adaptability	Agility	Flexibility	IT	Mutual trust	Performance
Adaptability	0.827					
Agility	0.331	0.862				
Flexibility	0.246	0.477	0.912			
IT	0.32	0.577	0.373	0.866		
Mutual trust	0.082	0.353	0.462	0.355	0.874	
Performance	0.296	0.652	0.568	0.518	0.595	0.752

IT: Information technology

That is, the square root of AVE for each construct was greater than the correlation coefficient of the other constructs, as illustrated in Table 4 (52,56). Moreover, since for each component, MSV < AVE and ASV < AVE, the discriminant validity of the components was confirmed. Furthermore, the results indicated that the subscales were not so highly correlated that they could form a construct and hence the components were not repetitive.

The goodness of fit (GOF) value for the model was 0.56, indicating a good fit for the model (57). The above statistic revealed that the proposed model was suitable for data collection. In general, it confirmed the relationships between the use of IT and mutual trust, flexibility, agility, adaptability, and the performance of HSC.

Different methods are used to test the model and its paths. One of the methods available is the GOF index and among the fit statistics, four indices of goodness of fit index (GFI), adjusted goodness of fit index (AGFI), root mean square error of approximation (RMSEA), and chi-square have been reported as 0.92, 0.90, 0.04, and 360.88, respectively. Finally, the chi-square to degree of freedom ratio was obtained as 1.38, indicating good fit of the model with the data. Table 5 demonstrates the model goodness of fit indices.

Table 5. Model goodness of fit indices

AGFI	GFI	RMSEA	P	Degree of freedom	Chi-square
0.90	0.92	0.03	0.001	260	360.88

AGFI: Adjusted goodness of fit index; GFI: Goodness of fit index; RMSEA: Root mean square error of approximation

Table 6 shows the results of investigation of the study hypotheses. Accordingly, the application of IT has positively influenced the agility, flexibility, and performance within the HSC framework, as the results indicated that the standardized path coefficients for hypotheses H1a, H1b, and H1c were within the acceptable range and the T-value was greater than the critical value of 1.96, confirming the hypotheses.

Similarly, the mutual trust has positively affected the flexibility in HSC, thus H2 was accepted as well because the T-Value was greater than the critical value and the value of the standardized path coefficient for H2 was 0.377, which was within the acceptable range, hence confirming the H2 hypothesis.

Moreover, the flexibility positively affected the organizational agility, adaptability, and performance as based on the results, the standardized path coefficients for H3a, H3b, and H3c were within the acceptable range and the T-values were higher that the critical value, thus the hypotheses were confirmed.

Furthermore, the organizational adaptability was not positively correlated with the HSC performance, and hypothesis H4 was rejected. Because the T-Value was 0.58 and lower that the critical value of 1.96, besides, the standardized path coefficient for H4 was 0.036, which was not within the acceptable range and did not confirm the hypothesis.

Finally, the agility of an organization positively influenced the performance of the humanitarian operations, and hence hypothesis H5 was confirmed, as the T-Value was greater than the critical value and the standardized path coefficient value for H5 was 0.493, which was within the acceptable range.

Conclusion

The current study was the first of its type carried out taking into account the relationship between the use of IT, mutual trust between organizations and individuals, flexibility, agility, and adaptability with the HSC performance. This study suggested a unique solution to bridge the research gap in the HSC literature; meanwhile, more experimental studies are required to be accomplished in the HSC management field.

The results indicated that the agility and flexibility in a HSC were along with the IT

Table 6. Summary of the results of assessment of the study hypotheses

Hypothesis		Standardized path coefficient	Statistic t	P	Result of hypothesis
H1a	Effect of IT on agility	0.464	9.333	< 0.001	Confirmed
H1b	Effect of IT on flexibility	0.419	3.858	< 0.001	Confirmed
H1c	Effect of IT on performance	0.551	2.207	< 0.050	Confirmed
H2	Effect of mutual trust on flexibility	0.377	6.233	< 0.001	Confirmed
H3a	Effect of flexibility on agility	0.304	4.982	< 0.001	Confirmed
H3b	Effect of flexibility on adaptability	0.546	3.661	< 0.001	Confirmed
H3c	Effect of flexibility on performance	0.509	4.021	< 0.001	Confirmed
H4	Effect of adaptability on performance	0.036	0.58	< 0.050	Rejected
H5	Effect of agility on performance	0.493	4.529	< 0.001	Confirmed

application, which in turn is correlated with performance. The results also showed that the application of IT was positively correlated with the agility, flexibility, and performance of the SC. Additionally, the mutual trust was significantly related to the HSC flexibility and the HSC flexibility had a positive effect on the adaptability, agility, and performance of the HSC. Ultimately, adaptability did not significantly affect the HSC performance. This study is expected to be useful for smaller organizations with guidelines to perceive the critical factors for improving the HSC performance.

The findings of the present study are in line with the results of previous studies (58). The results suggested that the IT application in HSC positively affected the agility, flexibility, and performance of the organizations involved in rescue operations to improve the conditions in the society. The findings of this study are also in agreement with those of other studies performed in the area of CSC. Youn et al. investigated the direct impact of mutual trust on flexibility (13). Similarly, the findings of this study revealed that there was a positive relationship between mutual trust and the SC flexibility, suggesting that mutual trust among the organizations involved in SC can be used as a "silver bullet" in many areas of the SC management (59).

Furthermore, the results of this study were indicative of the positive effects of the HSC flexibility on agility, adaptability, and performance of HSC. This is in line with the study by Dubey et al. (60). Flexibility can be achieved from the long-term planning, however adaptability stems from the short-term planning. In order to improve the adaptability of the organizations in the HSC network, the focus should be on the local culture, developing an attitude of sharing, and trust among organizations as well as responding to the environmental requirements.

This finding also confirms the results of the study by Maiers et al. (61), reporting that sharing information among members of the HSC is essential to improve its performance. Distribution of the proper information at the right place and time among the right individuals is one of the most important cases that should be regarded in knowledge sharing (61-64).
